

1 **ABSTRACT**

2 A fiber-optic waveguide comprises: 1) an evanescent waveguide fiber segment; and 2)
3 first and second longitudinally adjacent fiber segments joined to the ends of the evanescent
4 waveguide fiber segment and having cores that form, with the core of the evanescent waveguide
5 fiber segment, a substantially continuous core of the fiber-optic waveguide. The cladding layers
6 of the adjacent fiber segments substantially surround the cores thereof and substantially
7 transversely encompass an optical mode propagating through the fiber-optic waveguide. The
8 cladding layer of the evanescent waveguide fiber segment is asymmetrically disposed about at
9 least a portion of the core thereof, thereby yielding a coupling portion of the cladding layer
10 surface and enabling an evanescent portion of the propagating optical mode to extend
11 transversely beyond at least a portion of the coupling portion of the cladding layer surface of the
12 evanescent waveguide fiber segment. The fiber-optic waveguide may be incorporated into an
13 optical power control device by tangentially engaging the coupling portion of the cladding layer
14 surface of the evanescent waveguide fiber segment with a WGM optical resonator, thereby
15 enabling control of optical power transmitted through the fiber-optic waveguide via modulation
16 of WGM resonator properties and/or optical coupling thereto. The fiber-optic waveguide may be
17 fabricated by circumferentially asymmetric removal of cladding material from the evanescent
18 waveguide fiber segment. The cladding material may be removed by providing a mask for the
19 adjacent fiber segments and a portion of the length and circumference of the evanescent
20 waveguide fiber segment, and etching the cladding layer material.
